Linked List Problem – Call Log Merger (Phone App)

Problem Statement

A phone application maintains call history records using linked lists. Sometimes, call records are stored in two separate linked lists, such as personal calls and office calls, or calls collected from two different devices. Each call record contains the contact name and call duration in minutes.

The main objective of this project is to merge these two linked lists into a single linked list while maintaining the original order of records. The program should accept call details from the user, create two separate linked lists, merge them into one list, and display the final merged call log.

This project demonstrates the practical application of a singly linked list in managing phone call records efficiently. It helps students understand node creation, insertion, linked list traversal, and merging operations in C++.
